

The Bellman-Ford Algorithm

Andreas Klappenecker

Single Source Shortest Path Problem

Given a graph $G=(V,E)$, a weight function $w: E \rightarrow \mathbb{R}$, and a source node s , **find the shortest path from s to v for every v in V .**

- We allow negative edge weights.
- G is not allowed to contain cycles of negative total weight.
- Dijkstra's algorithm cannot be used, as weights must be nonnegative.

Bellman-Ford SSSP Algorithm

Input: directed or undirected graph $G = (V, E, w)$

for all v in V {

$d[v] = \text{infinity}$; $\text{parent}[v] = \text{nil}$;

}

$d[s] = 0$; $\text{parent}[s] = s$;

for $i := 1$ to $|V| - 1$ { // ensure that information on distance from s propagates

 for each (u, v) in E { // relax all edges

 if $(d[u] + w(u, v) < d[v])$ then { $d[v] := d[u] + w(u, v)$; $\text{parent}[v] := u$; }

 }

}

Running Time: $O(VE)$

Input: directed or undirected graph $G = (V, E, w)$

```
for all  $v$  in  $V$  {
```

```
     $d[v] = \text{infinity}; \text{parent}[v] = \text{nil};$ 
```

```
}
```

```
 $d[s] = 0; \text{parent}[s] = s;$ 
```

```
for  $i := 1$  to  $|V| - 1$  {
```

```
    for each  $(u, v)$  in  $E$  { // relax all edges
```

```
        if  $(d[u] + w(u, v) < d[v])$  then {  $d[v] := d[u] + w(u, v); \text{parent}[v] := u; }$ 
```

```
    }
```

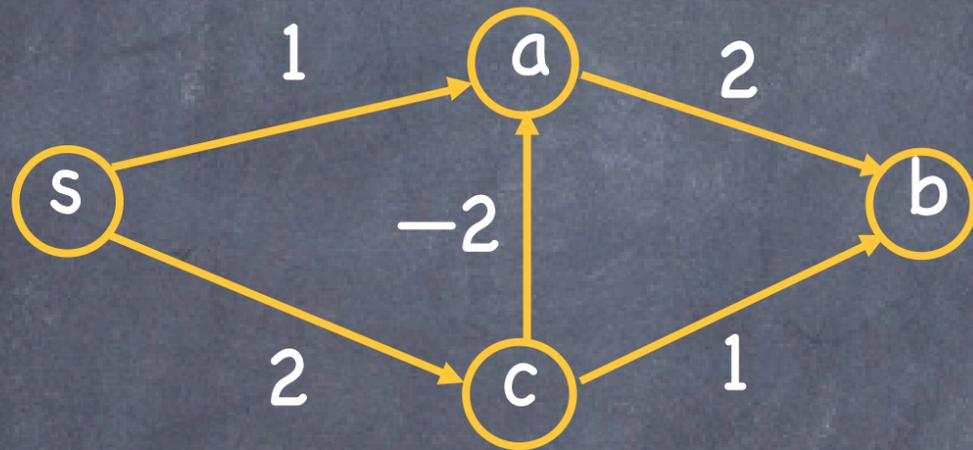

```
}
```

Init: $O(V)$

Nested loops:
 $O(V)O(E) = O(VE)$

Bellman-Ford Example

Let's process edges in the order
(c,b),(a,b),(c,a),(s,a),(s,c)

	Iteration			
Node	0	1	2	3
s	0	0	0	0
a	∞	1	0	0
b	∞	∞	3	2
c	∞	2	2	2

Information Propagation

Consider a graph on $n+1$ vertices:

$s \rightarrow a_1 \rightarrow a_2 \rightarrow \dots \rightarrow a_{n-1} \rightarrow a_n$

where each edge has weight 1.

Choose edges from right to left.
first. Then node a_i has correct
distance estimate after i^{th} iteration.

	Iteration				
Node	0	1	2	3	4
s	0	0	0	0	
a	∞	1	1	1	...
a	∞	∞	2	2	...
a	∞	∞	∞	3	...
a	∞	∞	∞	∞	...

Correctness

Fact 1: The distance estimate $d[v]$ never underestimates the actual shortest path distance from s to v .

Fact 2: If there is a shortest path from s to v containing at most i edges, then after iteration i of the outer for loop:

$d[v] \leq$ the actual shortest path distance from s to v .

Correctness

Theorem: Suppose that G is a weighted graph without negative weight cycles and let s denote the source node. Then Bellman-Ford correctly calculates the shortest path distances from s .

Proof: Every shortest path has at most $|V| - 1$ edges. By Fact 1 and 2, the distance estimate $d[v]$ is equal to the shortest path length after $|V| - 1$ iterations.

Variations

One can stop the algorithm if an iteration does not modify distance estimates. This is beneficial if shortest paths are likely to be less than $|V|-1$.

One can detect negative weight cycles by checking whether distance estimates can be reduced after $|V|-1$ iterations.

The Boost Graph Library

The BGL contains generic implementations of all the graph algorithms that we have discussed:

- Breadth-First-Search
- Depth-First-Search
- Kruskal's MST algorithm
- Strongly Connected Components
- Dijkstra's SSSP algorithm
- Bellman-Ford SSSP algorithm

I recommend that you gain experience with this useful library. Recommended reading: *The Boost Graph Library* by J.G. Siek, L.-Q. Lee, and A. Lumsdaine, Addison-Wesley, 2002.
